Gaet'ale- a reactivated thermal spring and potential tourist hazard in the Asale salt flats, Danakil Depression, Ethiopia

Sharad Master

Abstract

This paper serves to document a thermal spring, called Gaet'ale, that was reactivated in 2005, during the majorseismo-volcanic crisis in the Danakil Depression of the Afar region of northern Ethiopia. Many dead birds surrounding the spring attest to deadly gas emanations (almost certainly CO₂) coming from this spring, reminiscent of those from other volcanic lakes, and the Pamukkale springs in Turkey. Gaet'ale currently features among the tourist attractions of the Dallol region of the northern Afar, but it may pose a potentially dangerous, and even deadly, hazard for tourists and their guides. Some suggestions are made to help mitigate the risks, and to allow for sustainable geotourism in this environmentally sensitive region. These include ensuring that tour operators in the area are made aware of the hazards, and are communicating these to their tourist clients (who should also be aware of these hazards through websites, tour guidebooks and open-access scientific journals), and avoiding the areas closest to the lake, and periodic testing, with lit flames, for the presence of excess CO₂ in the area, with plans for quick and safe evacuation if needed. Guidelines for proper conduct are given for geotourists who are planning to visit the region, to ensure their health and safety in the vicinity of the thermal springs.

Keywords: Thermal spring, CO₂ emissions, Dead birds, Tourist hazard mitigation measures

Introduction

The Afar region of northern Ethiopia is one of the most tectonically active regions in the world, and is the site of abundant recent volcanic activity and seismicity (Wright et al. 2006; Darrah et al. 2012; Chernet 2013; Yirgu 2013).

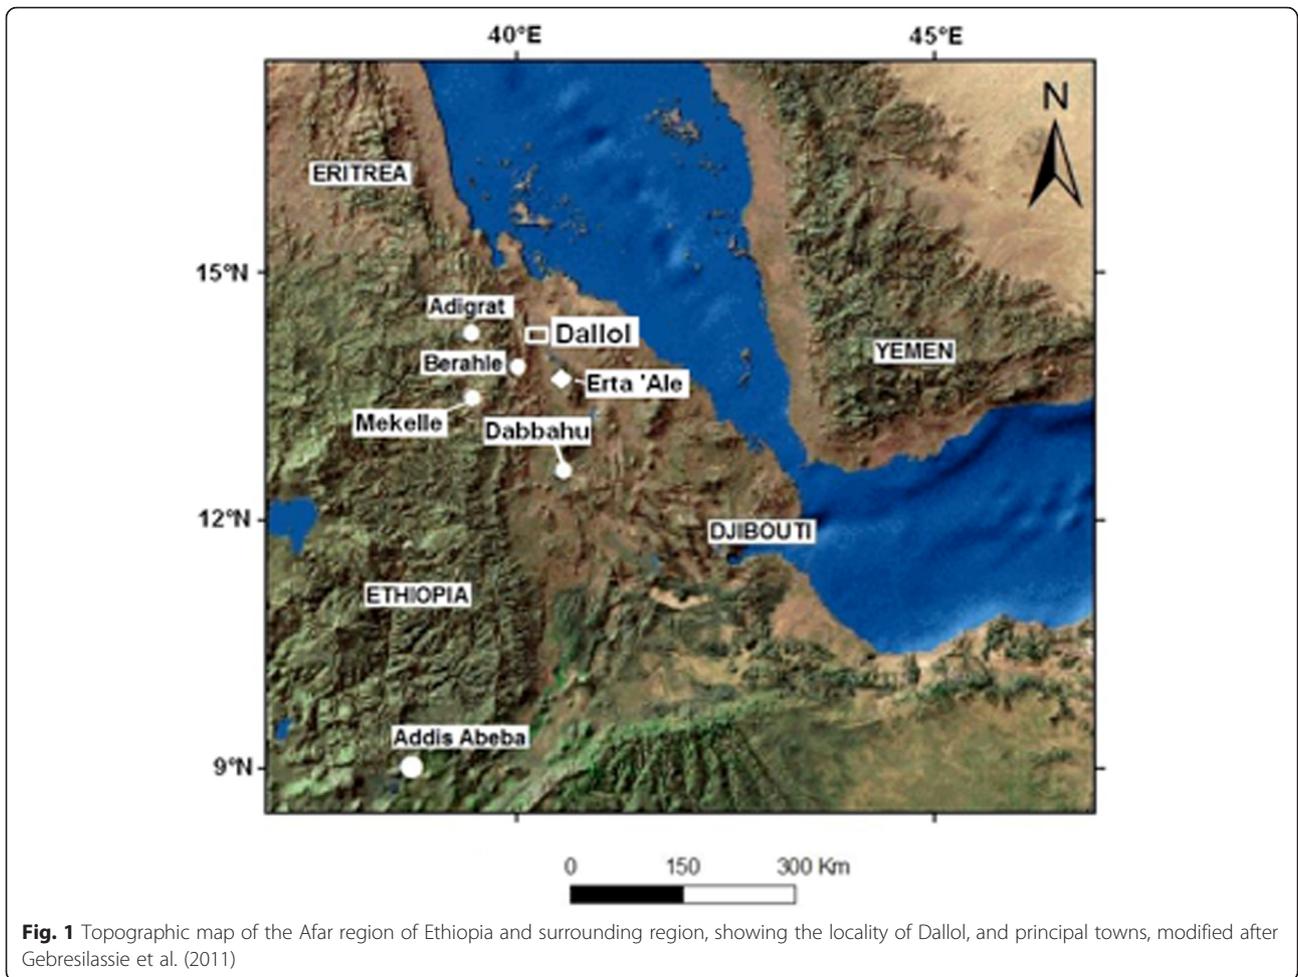

During the post-conference excursion to Afar (Kidane 2013), following the 24th Colloquium of African Geology in Addis Ababa (8–13 January 2013), the thermal springs (or hot springs) around Dallol (Figs. 1 and 2) were visited by an international group of geoscientists and other researchers. Observations made at Dallol, the Black Water spring (situated at 14°13'18.76" N, 40°17'10.33" E, Fig. 2), and at a relatively recently-formed spring (Figs. 3, 4, 5, 6), called Gaet'ale by the local Afar people, (which has not been monitored scientifically since it was formed), were supplemented by information gathered from local people and tourist guides. Many dead birds were observed

around the Gaet'ale springs and lake (Fig. 7), and locals have observed the birds dying due to gas emanations from the lake. These observations indicate that the Gaet'ale-spring and lake may pose a dangerous (and even potentially deadly) health hazard for human visitors. Here I describe the spring and lake, and propose measures that may be taken to mitigate the potential health risks.

Regional setting

The Danakil Depression is located near the triple junction of the Red Sea, Gulf of Aden and the Ethiopian Rift, formed by the rifting away of Arabia from Africa in Oligocene times, at about 24 Ma ago (Kursten 1972; Beyene and Abdelsalam 2005). The floor of the Danakil Depression is located about 120 m below sea level. The Dallol area is located 80 km northwest of an active volcanic ridge, which includes the volcano Erta Ale, which has a permanent lava lake (Barberi and Varet 1970, 1975). At Dallol, in the middle of a hot-spring area, there is a mound, called Mount Dallol, which is elevated 60 m above the surrounding plains which are situated at 120 m below sea level. On a satellite image (Fig. 2),

Mount Dallol resembles a volcanic mound with craters, although its surface geology is dominated by evaporite rocks and hydrothermal spring deposits, with no volcanics (Holwerda and Hutchinson 1968; Darrah et al. 2012).

The area surrounding Dallol is occupied by Lake Asale, an ephemeral salt lake, which sits atop a 2-km thick evaporite sequence (Behle et al. 1975), which is dominated by halite and sylvite, together with subordinate layers rich in carnallite and kainite (Holwerda and Hutchinson 1968). The evaporite sequence formed when an arm of the Red Sea was isolated by an uplifted horst

block, causing the sea to evaporate completely (Kursten 1972; Beyene and Abdelsalam 2005). The oldest rocks in the region are deformed Neoproterozoic arc terrains that form the local basement, exposed on the flanks of the rifted southwestern margin of the Ethiopian Rift. This basement is overlain by rocks of the Mesozoic Mekelle Basin, comprising the Jurassic Adigrat sandstones and Antalo limestones, and the Cretaceous Amba Aradom sandstones (Beyth 1972). The Mekelle Basin, in turn is overlain by late Cenozoic (Eocene to Recent) mafic volcanic rocks of the Afar Traps and the so-called "Stratoid Series" (Barberi and Varet 1975), forming the floor of the Danakil Depression, which is overlain by the Danakil evaporites (Bosworth et al. 2005). The ephemeral Lake Asale is found on the surface of the evaporites- it gets recharged and resurfaced by sheetfloods and groundwater emanating from the Ethiopian highlands. The Dallol springs have evaporitic tufas deposited around them. The Black Water and Gaet'ale springs are found erupting through the evaporites around the Dallol mound. The

spring waters gush up under pressure, and form small fountains or jets which bubble up from the surface of the small lakes that are formed around the springs.

Gaet'ale spring and lake

The spring of Gaet'ale is situated at 14°12'48.8" N, 40°19'16" E, 3.8 km southeast of the Dallol spring and crater. The spring feeds a roughly circular lake which is about 70 m in diameter (Fig. 3). It is not known when the lake was originally formed, but freely available high resolution Landsat satellite imagery taken on 6 February 2003 on Google Earth shows that the lake existed then in much the same shape and size as at present. The waters of the lake are yellowish orange to reddish orange in colour, from dissolved iron salts, and do not have any

Fig. 7 A close-up view of four dead birds (also seen in Fig. 6), partly enclosed in salt, right on the edge of the Gaet'ale spring lake. The largest bird, in the centre, is a black-headed heron (*Ardea melanocephala*). The other birds cannot be positively identified, but are probably ravens or swifts

sulphurous odour (Figs. 4, 5, 6). The spring water bubbles up powerfully in several small fountains, and is bright yellow in colour (Fig. 5). The lake level is about 1.5 m below the level surrounding salt flat of Asale salt lake. About half a metre above the lake level, there is a flat step-like terrace made of light-coloured halite, which is overlain by a metre of slightly darker yellowish-brown sediment consisting of a mixture of salt and mud, overlain by a surficial layer of light-coloured halite about 10 cm thick, which forms a scalloped ledge jutting out around the perimeter of the lake, with an undercut fringe where the underlying muddy salt has been dissolved away (Fig. 6). The surficial salt is overlain by a thin veneer of dark sediment. Around the margins of the lake, which are raised very slightly above the surrounding flat salt plain, there has been deposited a ring of debris made up of wood and plant material, some of it burnt to charcoal, and mixed in with this were artefacts of recent human origin, such as rubber sandals. Among this debris were the decayed remains of several locusts. According to Yahya our tour guide, the debris washed in by rains coming from the highlands, which produce sheetfloods carrying this material in from near human settlements, such as Afar villages which are found sparsely scattered in this area.

The following information was obtained from tour operators, and residents of Ahmedela, the nearest inhabited village to the Dallol springs. The spring activity started anew following an earthquake in January 2005. At the start, there was a geyser fountaining up to 3 m high, and it lasted for 3 years. The water was not hot, and not very acid, since people tasted it. "The Black Water is strongly acidic, but this one is not". Our informant Ali Mohamed (pers. comm., 19 January 2013) personally observed birds dying due to gases released from the spring. The birds ate insects that lived in the spring. The birds do not die all the time, but at certain distinct periods (i.e., the mortalities are not continuous).

In 2004, a dyking event, accompanied by a 5.5 magnitude earthquake, took place some 12 km SSW of Dallol (Nobile et al. 2012). The earthquake or earthquakes of 2005, which resulted in the formation of the Gaet'ale spring and lake, were part of a major seismo-volcanic crisis which affected the Danakil Depression in the Afar in late 2005, with a major dyking event, accompanied by lots of seismicity (Wright et al. 2006; Ayele et al. 2007; Yirgu 2013). There were 15 earthquakes greater than magnitude 5, a small explosive silicic volcanic eruption, and a 60 km-long dyking event in the Dabbahu area (Fig. 1) some 200 to 250 km south of Dallol (Ayele et al. 2007, 2009). The volcano-seismic crisis produced stresses which affected the Erta 'Ale volcano (Fig. 1) (Ayele et al. 2007), and it is likely to have affected the Dallol region as well. While earthquake-induced fluid

flow has been observed in other areas such as Japan, and has been explained by the dilatancy-fluid diffusion model (Nur 1974), it is more likely that the Gaet'ale spring was produced by seismically-induced reorganization of hydrothermal plumbing connected to a near-surface magma chamber of the nearby Dallol crater (Carniel et al. 2010), which is very active, and has produced a phreatic eruption in 1929, and a recent ash cloud in January 2011 (Chernet 2013). Strong turbulent activity of the Gaet'ale spring, which had turned the waters into an opaque, muddy orange colour, was recorded in 2012 (Fig. 5).

At least ten dead birds were seen all around the circular spring-fed lake, and all of them were well-preserved, having effectively been pickled by the hypersaline brine of the lake. The largest bird was a black-headed heron (*Ardea melanocephala*, Ash and Atkins 2009), which was partly covered in salt. The other birds, which were in various states of entombment by the surrounding salt, were black birds, with short white beaks, somewhat resembling the Ethiopian raven (*Corvus edithae*), but smaller, and other small birds with barred wings which have not been positively identified, but are possibly swifts, which have been recorded around Dallol and the Danakil in general (Thesiger and Meynell 1935; Aerts et al. 2006). Some appeared to have died very recently, being unaffected by salt, while others had been around for a while, and were partly encrusted or buried by salt. A number of dead insects were found, including a 2.5 cm long glider beetle, a 3 cm long locust, and two quite decomposed moths. Arachnids of the order Solifugae (commonly known as "camel spiders") are also known in the Dallol area (Aerts et al. 2006). The insects and arachnids are the main attraction for birds in the springs in the Dallol area. Two dead birds have also been noted around the Black Water spring in January 2011 by Maxwell Matongo, an exploration geologist who was working in the area (Matongo, personal communication, 2 July 2013).

Chemistry and origin of the gaseous emanations from Gaet'ale

The water temperature at Gaet'ale is not very hot to the touch, unlike the nearby Black Water spring, where the temperature is very hot, as tested by our group, and was measured as 70 °C (Darrah et al. 2012). The water has agreeable or soapy feeling, but this is not due to oil, as surmised by Gebresilassie et al. (2011), but due to supersaturation in dissolved salts, which precipitate readily on cooling. The bright yellow colour of the spring waters in the Dallol area are due to the iron-chlorocomplex ferriochlorate III (Pittwell 1972a, b, 1973). Gebresilassie et al. (2011) reported on the chemistry of these waters, from the spring at UTM location 0640078/1572390, (i.e., Gaet'ale) which had pH of 3.50-3.95, Total Organic Carbon (TOC) contents of between 36 and

409 ppm, Total Dissolved Solutes (TDS) of 96 to 110.4 ppm, SO_4^{2-} contents of 21 to 117 ppm, and sulfide contents of 40-960 ppb. The low TOC contents confirm that the greasy feeling of the spring was not due to oil.

It is well known that CO_2 is produced copiously from the volcanoes of the Afar, such as Erta'Ale (Tazieff et al. 1972; Le Guern et al. 1979; Gerlach 1980, 1981, 1989; Sawyer et al. 2008) and volcanically-derived CO_2 is one of the major sources of dissolved bicarbonate in Ethiopian Rift spring waters (Gizaw 1996). The hot springs at Dallol were shown to be enriched in ^{18}O due to isotopic exchange with the volcanic rocks (Gonfiantini et al. 1973). Recently, a detailed isotopic and geochemical study of the spring waters around the Dallol hydrothermal system has revealed the presence of primordial ^3He among the gaseous components, revealing the magmatic origin of the gases, including the abundant CO_2 (Darrah et al. 2012). The Dallol hydrothermal system has been regarded as the result of interaction and assimilation of salt deposits by intruding mafic magmas, resulting in the formation of iron chloride sublimates which mix with meteoric waters heated by the volcanism, and ultimately precipitate iron-rich salts which give the bright colours to the Dallol deposits (Master 2013). The dead birds at Gaet'ale and Black Water were most probably killed by CO_2 emanations, such as were observed coming out of the Dallol crater in the first week of January 2011 (Chernet 2013).

CO_2 emanations at Gaet'ale as a potential health hazard for tourists

Volcano and geothermal spring tourism is a growing component of geotourism, and is enjoying an increasing popularity worldwide (Erfurt-Cooper and Cooper 2010). It is becoming more popular in Ethiopia, where the major drawcards are the volcano Erta 'Ale, with its permanent lava lake, and the Dallol springs, with their spectacularly colored waters, mineral salts, and landforms (Edelman and Roscoe 2010). Geotourism has been defined as tourism that enhances or sustains the geographical character of a place and its environment, as well as its culture, aesthetics and heritage, and it also incorporates the idea of sustainable tourism, in which destinations should remain unspoilt for future generations (Lew 2002). In order to make volcanic landscapes sustainable as geotourism destinations, the potential hazards posed by these regions need to be recognized and publicized (Baxter et al. 1986; Hansell and Oppenheimer 2004; Hansell et al. 2006; Heggie 2009). Volcanoes and associated volcanic springs and emanations are a potential human and animal health hazard which has been documented in many places since ancient times (Heggie 2010; Baxter 2005, 2010). A wide range of hazards are found in volcanic areas and include lava flows, tephra and ash falls from volcanic eruptions, associated earthquakes, landslides, mudflows and

lahars, and volcanic gas emissions, volcanic laze, and acid rain (Hansell et al. 2006; Heggie 2009).

One of the major hazards in volcanic regions is posed by volcanic gas emanations, which may originate from lava lakes, volcanoes, volcanic lakes, faults and fissures, and from hot springs (Baxter et al. 1990, 1999; Hansell and Oppenheimer 2004; Hansell et al. 2006; Zuskin et al. 2007; Heggie 2009). The volcanic gases include CO_2 , SO_2 , HCl, H_2S , HF, CO, N_2 , H_2 , He, CH_4 , Rn, together with volatile elements such as Pb and Hg.

Carbon dioxide (CO_2) is an abundant volcanic gas which is emitted during volcanic eruptions and in geothermal areas, and is particularly insidious and dangerous because it is odorless, and denser than air (Heggie 2009). On the 20th February 1979, a phreatic eruption of the Dieng volcano on Java, Indonesia, caused a CO_2 gas emanation which overflowed from the crater and rolled downhill, killing 142 people (Le Guern et al. 1982; Allard et al. 1989). In the volcanic regions of Cameroon, deadly releases of CO_2 gas resulted in the deaths of 37 people at Lake Monoum in 1984, and about 1700 people at Lake Nyos in 1986, in addition to numerous other animals such as cattle (Sigurdsson 1987; Sigurdsson et al. 1987; Baxter and Kapila 1989; Baxter et al. 1989; Holloway 2000). The CO_2 emanations of lakes Nyos and Manoum resulted from trapped volcanic-derived gas released from sediments at the bottom of deep stratified volcanic lakes, and the release may have been triggered by landslides or some other unknown mechanism (Holloway 2000). Other volcanic areas that are prone to hazardous gas emissions include the Roman volcanic province (Beaubien et al. 2003; Carapezza et al. 2003), and places where geotourists are especially vulnerable, such as the Furnas volcano, Azores (Baxter et al. 1999; Dibben and Chester 1999), the Hawaii Volcanoes National Park (Stephenson et al. 1991; Heggie and Heggie 2004; Heggie 2005; Heggie et al. 2009), and Mammoth Mountain, a dormant volcano and popular recreation area in California (Sorey et al. 1998). In the case of Gaet'ale, the CO_2 gas is also of volcanic origin, but here it is derived from degassing from a near-surface magma chamber, which has triggered fumarolic and phreato-magmatic activity in the past (Darrah et al. 2012; Chernet 2013).

Comparisons may be drawn between Gaet'ale, which has been demonstrated to be deadly to birds, and other deadly springs where volcanically-derived CO_2 emanations have been fatal to animals. Weed (1889) and Jaggar (1899) (cited by Stupfel and Le Guern 1989) described how CO_2 emanating from a volcanic spring in the Yellowstone National Park, flowed into a hollow (since it is heavier than air), where it acted as a death trap for several bears who died after inhaling the deadly gas. Another analogy exists between the Gaet'ale springs and the CO_2 -rich springs at Pamukkale, Turkey (Altunel and

Hancock 1993). The Pamukkale springs are situated next to the ancient Phrygian town of Hierapolis, which was famed for its thermal springs, which were described by the classical geographer Strabo (c. 65 BCE- c. 24 CE). In April 2013, an Italian archaeological team led by Francesco d'Andria announced the discovery, in the town of Heirapolis, of the Ploutonion, a temple dedicated to Pluto, Greek god of the underworld, and regarded in ancient times as the gates of Hades (D'Andria 2013; Pfanz et al. 2014). Strabo (1924, Book XIII, Chapter 4, Section 14), describing the Ploutonion, reported that "this space is full of a vapor so misty and dense that one can scarcely see the ground. Any animal that passes inside meets instant death. I threw in sparrows and they immediately breathed their last and fell." D'Andria reported that he could see the cave's lethal properties during the excavation. He stated that "several birds died as they tried to get close to the warm opening, instantly killed by the carbon dioxide fumes" (Walsh 2013).

Although they are situated in an inhospitably hot, unrelentingly bleak, hostile and barren salt plain, devoid of any shade or vegetation, the yellow bubbling springs of Gae'tale act as a magnet for tour operators who bring increasingly more geotourists to the region around the Dallol hot springs and the active volcanoes of Danakil (Edelman and Roscoe 2010; Weber 2015). On the website Panoramio (2015), around 100 photographs of the Dallol hot springs have been posted by dozens of visitors, and five different people have posted photographs of the spring and lake at Gaet'ale, as of 29th May 2015. This is evidence of the growing popularity of Gaet'ale as a tourist destination in the Dallol region. Many visitors have also been to Black Water spring. A new road under construction linking Mekelle with the Dallol potash mining region is certain to increase the number of tourists to this area. The episodic and intermittent nature of the CO₂ eruptions that have caused mass fatalities of birds around the Gae'tale and Black Water springs are of unknown intensity and duration, and they may also pose a threat to the health and wellbeing of human visitors (tourists and their guides) who come to visit this lake (see below). Tour operators and visitors must be made aware of the hazards associated with the deadly springs

of Gaet'ale. Precautions must be taken to speedily and safely evacuate the immediate vicinity of the spring and associated lake, where heavy CO₂ may accumulate, should the need arise.

It must be borne in mind that CO₂ is colourless and has no smell, and its presence is not easily detected. Because it is heavier than air, it tends to accumulate in hollows and depressions in volcanic areas (Allard et al. 1989; Stupfel and Le Guern 1989; Baxter et al. 1989, 1990, 1999; Baxter 2010). The effects of increasing CO₂ concentrations in the air range from a shortage of breath, to dizziness, loss of consciousness and death (Ikeda et al. 1989; Hathaway et al. 2004; Hansell and Oppenheimer 2004; Hansell et al. 2006; Cantrell and Young 2009) (Table 1). In some instances, excess CO₂ inhalation can lead to toxic sensorineural dysosmia resulting in olfactory distortions (parosmia) and hallucinations (phantosmia), and people have reported smelling "rotten gas" (H₂S), and other smells, as well as narcoticeffects (Seevers 1944; Feldman et al. 1986). Acidic volcanic gas (volcanic laze) can be distinguished from carbon dioxide as it causes severe inflammation of the airways and pulmonary oedema (Heggie et al. 2009), while inhalation of carbon monoxide and nitrous oxides produces carboxyhaemoglobinaemia and methaemoglobinaemia, respectively (Baxter et al. 1989; Hansell and Oppenheimer 2004). These two conditions arise when CO and CH₄ respectively combine with haemoglobin in the blood, and having a greater affinity for haemoglobin than does oxygen, they effectively cause the body to be starved of oxygen, with fatal consequences (Manning et al. 1981; Baxter et al. 1989).

Sustainable geotourism and health risk mitigation at Gaet'ale

In Ethiopia, the volcanic regions of Erta 'Ale, Dallol and Gaet'ale are not (as yet) part of a national park, so it is difficult to enforce any kind of rules and regulations with regard to visits to potentially dangerous places. These regions are very remote, and only accessible with rugged specially equipped vehicles, and most visits are arranged, organized and carried out by adventure tourism companies based in the Ethiopian cities of Addis Ababa and

Table 1 The effects of increasing CO₂ concentrations in the air on human health (after Ikeda et al. 1989; Hathaway et al. 2004; Hansell and Oppenheimer 2004; Hansell et al. 2006; Cantrell and Young 2009)

% CO ₂ in air	Physiological effects on humans
5	perceptible increase in respiration
6 to 10	shortness of breath, headaches, dizziness, sweating, general restlessness, visual disturbances, tremors
10 to 15	impaired coordination and abrupt muscle contractions, tachycardia
20–30	loss of consciousness and convulsions
>30	can result in death in 1–10 min

Mekelle (and a few from Europe). Tour operators cannot be relied upon to provide information that may potentially turn tourists away, and tourists themselves, even in well regulated national parks such as in Hawaii, not infrequently disobey rules and specific instructions, leading to injuries or death (Heggie and Heggie 2004; Heggie 2005). Because of the remoteness of these features, and the lack of oversight by regulatory authorities, the commonly visited geographic features in the Danakil Depression, such as the volcanoes, hot springs and salt formations, do not have any signs or warnings. One of the major drawbacks of the Danakil region is the wild and “unspoilt” nature of the natural environment. In this area any kind of signage or artificial barriers to access will result in despoiling and degrading the aesthetic experience of pristine wilderness, which is one of the main attractions for eco- and geotourists to the area in the first place.

Perhaps the best way of making people aware of the potential dangers of these volcanic springs is through tourist websites, guidebooks and in open-access scientific journals, which are easily accessible through web-based searches. The majority of adventure tourists to remote places like the Danakil Depression are likely to have done research online and in guidebooks, before embarking on these (usually costly) geotourism adventures.

Periodic testing of the air by checking whether a flame burns (e.g., Stupfel and Le Guern 1989), may be an easy way of detecting the presence of excess CO₂ near the Gaet’ale springs. However, this must be done in an environmentally sensitive way (e.g., use must be made of cigarette lighters, rather than matches, which tend to be thrown away, and will end up accumulating as rubbish around an extremely fragile site, where nothing decays). Cigarette lighters themselves, like all other waste, must be carried away and disposed of properly, and no trace of human artefacts should be left at this site, as in all other sites in the region of the Dallol springs and Asale salt lake, in order to preserve the pristine nature of the environment and make it sustainable for tourism. People should be warned not to walk on the lower terrace immediately surrounding the lake, where CO₂ may accumulate, and where all of the dead birds were found, but to observe it from the upper terrace, where the threat of carbon dioxide poisoning is much reduced. The flat and exposed nature of the surrounding plains would favor the dilution and dispersal of CO₂ eruptions from these springs, unlike the situation in hilly volcanic regions where CO₂ is funneled down topographic gradients.

The Black Water spring is more open, and does not have a stepped hollow depression like Gaet’ale, and hence there is much less of a threat of toxic CO₂ accumulation there, even though deadly vapours are occasionally given off, as attested by the observations of dead birds there in the past. Nevertheless, the Black Water

spring is still quite dangerous for anybody who goes near its edge, because of the risk of sinking into hot mud, or of falling into the spring-fed lake itself. Prof. Jacques Varet recounted (pers. comm., January 2013) that in the early 1970’s, he had approached the edge of the Black Water spring to sample it, and he collapsed into hot saturated mush, which behaved very much like quicksand, and only saved himself by falling backwards with his arms outspread, in order to distribute his weight more widely. He suffered serious burns on his lower legs, from being scalded by the extremely hot spring waters.

The Danakil Depression and its tourist attractions are not outside of government control and interest. In 2012, a number of foreign tourists were abducted from Dallol by Eritrean-based rebels and taken across the border to Eritrea, where they were killed. Subsequently, the Ethiopian army made reprisal raids to eliminate the rebels, and have posted armed guards to accompany groups of tourists visiting the sites of Erta ‘Ale and Dallol. This was the case during the January 2013 excursion to the Afar and Danakil Depression as part of the 34th Colloquium of African Geology (Kidane 2013). There is thus a potential for intervention by the Ethiopian Ministry of Tourism to liaise with tour operators in the area, to distribute pamphlets and warnings about the potential dangers of the active volcanoes and CO₂-emanating volcanic hot springs in the region.

Tourists contemplating or planning visits to the Danakil Depression and its volcanic geotourist destinations, especially the thermal springs, are advised to abide by the following guidelines for their own health and safety, to ensure that they are able to enjoy the experience of travel to this unique part of the earth, without undue exposure to potentially harmful and even deadly risks and hazards:-

1. Never go near the edge of any of the hot springs, such as Gaet’ale, Black Water, or Dallol springs. The surrounding salt may be brine-saturated and very weak, and may not support the weight of a person.
2. Do not try to sample the spring waters- since falling in could expose you to extreme scalding, in hot acidic waters (pH of Gaet’ale is around 3.5 to 4, Gebresilassie et al. 2011).
3. At Gaet’ale, do not descend to the lower terraces immediately surrounding the spring. This is where CO₂ tends to accumulate, and it has killed many birds, and may potentially be fatal to humans.

The deadly springs of Gaet’ale deepen the fascination of this region, and their potential for dangerous CO₂ gas eruptions would add a touch of irresistible attraction for the particular breed of adventure tourists who are drawn to such areas. These springs may be safely visited if precautions are taken, and people are prevented (or

dissuaded, by easily accessible information) from climbing down to the water's edge, where the highest risks of CO₂ accumulation and poisoning are present.

Competing interests

Acknowledgements

I am grateful to members of the multidisciplinary international group of researchers that visited the Gaet'ale spring on 19 January 2013, for discussions, especially Tesfaye Kidane (excursion leader), Kurt Klima, Monica Klima, Jacques Varet and Frances Williams. I thank Tamiru Abiye for discussion concerning CO₂ and hydrology in the Ethiopian Rift system. I also thank our guides Yahya of Ethio-Der Expeditions, and Ali Mohamed of Ahmedela village, for their input and information. Finally, I am indebted to Maxwell Matongo for the information concerning dead birds at Black Water spring. The School of Geosciences, University of the Witwatersrand, provided funding for this research.
